64425

Dilithologic breccia

14.62 grams

Figure 1: Surface T, of 64425. Sample is 4 cm long. NASA S88-46191.

### Introduction

Sample 64425 was sieved from soil 64420 which was collected from the bottom of a 25 cm deep trench at the bottom of a small double crater on the rim of a 15 meter crater (Cinco 'a') on Stone Mountain. It is part anorthosite and part impact melt (figure 1). Most surfaces have micrometeorite craters, indicating it had once been a surface sample.

It is thought that dimict breccias similar in appearance to 64425 (e.g. 64435, 64475) may be ejecta from South Ray Crater (James and Lindstrom 1991).

### Petrography

Walnut sample 64425 was described and analyzed by James and Lindstrom (1991). They noted it was made up of two prominent lithologies: a) granulated ferroan anorthosite (white) and b) fragment-laden impact-melt

(dark). The dark melt rock invades the white anorthosite and forms a network of thin veinlets that envelop the anorthosite fragments. The anorthosite is cataclastic with grain size from 10 microns up to 1 mm. There is only minor mafic minerals content (orthopyroxene and augite).

The melt rock varies from subvitreous to very fine grained intersertal. It has from zero to 50 % clastic material, mostly plagioclase, with minor globules of iron intergrown with troilite and or schreibersite.

### Chemistry

There is a wide range of chemical composition between the two major lithologies in 64425 (table 1 and figure 3).

Figure 2: Surface B, of 64425. Sample is 4 cm long. NASA S88-46192.
